XV. Los Angeles (ver2002)

Basalt, 698 grams
2 pieces (*so far*)

Introduction

Bob Verish found two stones, with attached fusion crust, weighing 452.6 g (figure XV-1) and 245.4 g (figure XV-2) respectively, while he was cleaning out a box of rocks in his backyard (in Los Angeles, California). He took them to UCLA where he learned they were from Mars! The specimens may have been collected ~20 years ago, somewhere in the Mojave Desert.

Petrography

Los Angeles has a coarse-grained (2-4 mm), basaltic texture and mineralogy closely resembling that of QUE94201 and the coarse-grained portions of Zagami (Rubin *et al.* 2000; Mikouchi 2001). Xirouchakis *et al*. (2002) describe the texture of Los Angeles as that of a microgabbro, dominated by relatively large anhedral to subhedral grains of pyroxene (2 mm) and subhedral to euhedral plagioclase. Xirouchakis *et al.* (2002) provide a detailed crystallization history, including a discussion of the T – pO_2 trend.

Approximately 5-10% of the sample consists of ~50-200 micron-sized, patches of a fine-grained vermicular to micrographic intergrowth of fayalite, hedenbergite and silica that (at first) appears to be the breakdown product of pyroxferroite (Rubin *et al*. 2000; Aramovich *et al.* 2001). However, Xirouchakis *et al.* (2002) argue that the complex, fine-grained, late-stage intergrowths are a natural occurrence of the slow crystallization history.

Photomicrographs of thin sections illustrated in Mikouchi (2001) and Greenwood *et al*. (2001), best illustrates the interior texture. Photos of bulk samples can also be seen at http://www.jpl.nasa.gov/snc/la.html.

The samples appear to have some calichi attached (Rubin), and may have been collected from a “dry” lake bed. However, the interior of the samples appears to be unweathered.

silica	5	2.7	1.7
fayalite	4	1.9	
K-rich felsic glaaa	2	3.7	
Ca-phosphate	3	2.3	1
pyrrhotite	0.7		
oxides	3	1.7	1
fusion crust			1.5

Mineral Chemistry

Pyroxene: Pyroxenes in Los Angeles are present as low-Ca pigeonite and high-Ca augite, zoned to become relatively Fe-rich (figure XV-3). $En_{50}Wo_{10}$ and $En_{40}Wo_{33}$ zoned to En_5Wo_{15}. Wadhwa *et al.* (2001) have determined the REE contents of pyroxenes. Pyroxenes exhibit relatively thick (0.7 to 4 micron) exsolution, indicating slow cooling (Warren *et al*. 2000; Mikouchi 2001; Xirouchakis *et al*. 2002).

"Pyroxferroite": Rubin *et al.* (2000) have studied the low-pressure, breakdown products (symplectite ?) of inferred "pyroxferroite" in Los Angeles.

Feldspar: The high content (~50%) of maskelynite ($An_{41}Or_4$ to $An_{58}Or_1$) in Los Angeles makes it unique among Martian meteorites. A few grains show normal core to rim chemical zoning, but many grains are reversed zoned, Ca-rich near the pyroxene (Mikouchi 2000). A few grains of plagioclase are still birefringent, indicating that Los Angeles was less shocked than Shergotty.

Phosphates: Mikouchi (2001) and Xirouchakis *et al*. (2002) have determined the composition of the phosphates. Wadhwa *et al*. (2001) have determined the trace element contents of apatite and whitlockite.

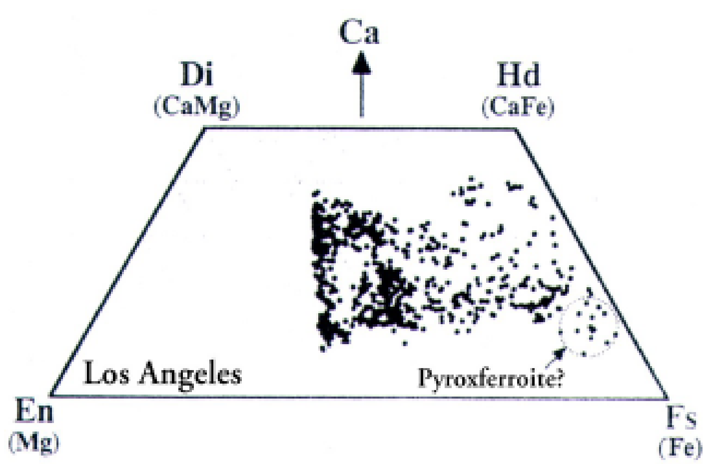

Figure XV-3. *Pyroxene quadrilateral of Los Angeles (from Mikouchi 2001, Antarct. Met. Res. 14, 5).*

Silica: Large grains (up to 1 mm) of silica are found in Los Angeles (Mikouchi 2001). Fine-grained intergrowths of silica and fayalite or hedenbergite are also observed.

Oxides: Ulvöspinel is the dominant opaque phase in Los Angeles (Mikouchi 2001). Xirouchakis *et al.* (2002) give an analysis of titano-magnetite. Ilmenite exsolution is found in the ulvöspinel – titano-magnetite.

Pyrrhotite: Rubin *et al*. (2000), Mikouchi (2001) and Xirouchakis *et al*. (2002) all report trace pyrrhotite – usually as "blebs" within the oxides.

Olivine: Fayalite (Fo5) is found intergrown with other phases in symplectite and as thin (5 to 15 micron) rims on titano-magnetite.

Carbonates: Graham *et al.* (2000) studied the carbonates on surfaces of Los Angeles.

Whole-rock Composition

The chemical composition of the Los Angeles meteorite is reported in Rubin *et al.* (2000) (see also GSA data repository item #2000107). Los Angeles is more differentiated than other Martian basalts (table XV-1). It has higher Fe/Mg ratio and higher trace element content. The REE pattern is flat, similar to that of Shergotty and Zagami, and unlike that of QUE94201 (figure XV-4).

Radiogenic Isotopes

Nyquist *et al.* (2000) have dated Los Angeles by Rb-Sr at 165 ± 11 Ma (figure XV-5). Nyquist *et al*. (2001) reported a Sm-Nd age of 172 ± 8 Ma.

Cosmogenic Isotopes and Exposure Ages

Terribilini *et al*. (2000) calculated an exposure age of 3.1 ± 0.7 Ma from ^{81}Kr measurements. Nishiizumi *et al.* (2000) determined a ^{10}Be exposure age of 3.0 ± 0.4 Ma and ^{21}Ne exposure age of 3.0 ± 0.2 Ma. Nishiizumi *et al*. (2000) also report the ^{36}Cl and ^{26}Al concentrations.

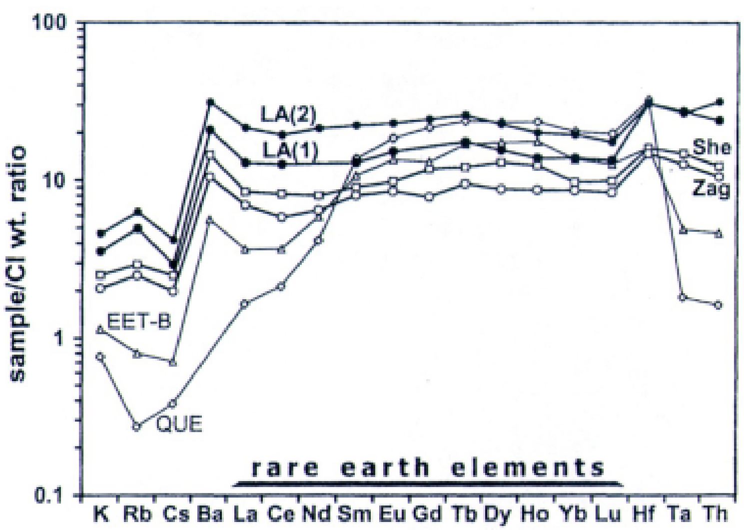

Figure XV-4. *REE diagram for Los Angeles (from Rubin et al. 2001, Geology **28**, 1013).*

Magnetics

The Los Angeles meteorite appears odd magnetically (Rochette *et al*. 2001). Saturation magnetization (M_s) is as high as 1.2 Am^2/kg. (*one must be careful not to magnetize a sample from Mars with a hand magnet*).

Other Isotopes

Garrison and Bogard (2000, 2001) have studied the noble gases extracted from Los Angeles and found isotopic evidence for Martian "interior" component, but little "atmospheric" in the sub-sample that they studied. Busemann and Eugster (2002) show that substantial, fractionated, terrestrial air is adsorbed on weathered meteorites from dessert regions, including Los Angeles.

Rubin *et al.* (2000) reported the oxygen isotopes in bulk Los Angeles ä^{18}O = +4.53‰, ä ^{17}O = +2.53‰ and Ä^{17}O = +0.17‰.

Processing

About 30 grams of the Los Angeles meteorite is at UCLA, 30 grams at Arizona State, 19 grams at the Smithsonian and about 11 grams remains with the finder. Mikouchi credits UCLA for the loan of the thin section he studied. Xirouchakis *et al.* credit the American Museum of Natural History for a piece (5103) of stone 1.
